## VIDEO DECODING METHOD AND DEVICE INCLUDING A DEBLOCKING FILTERING STEP.

## FIELD OF THE INVENTION

The present invention concerns a method for decoding data representing a sequence of pictures previously divided into blocks and coded, including, for each successive picture, at least the steps of :

- decoding said data ;
- filtering the decoded data ;

said filtering step being applied to at least one pixel component of a selected segment of consecutive pixels located on a single line or column of the current picture and on both sides of a boundary between two blocks, so that the boundary divides the segment in two parts.

The invention also concerns a corresponding device. This invention may be used particularly in low bit rate applications such as videophony or videoconferencing.

## BACKGROUND ART

Coding a sequence of pictures comprises different steps. Each picture is composed of a bidimensional array of picture elements or pixels, each of them having luminance and chrominance components. In order to be encoded, the picture is subdivided into blocks of pixels. A discrete cosine transform (DCT) is applied to each block of the picture. The coefficients obtained from this DCT are rounded to the closest value given by a fixed quantisation law and then quantised, depending on the spatial frequency within the block that they represent. Quantisation is, in data transmission, one of the steps for data compression and is a lossy data treatment.

During the decoding, the data are successively treated by inverse-quantisation and inverse discrete cosine transform, and finally filtered before being displayed.

The quantisation errors introduced by the quantisation of the DCT coefficients in the coding have for main result the occurrence of blocking artefacts at the boundary of two blocks. Since each block is treated separately during the coding, the coefficients obtained from the DCT are indeed quantised differently for the two blocks. Visually a kind of grid appears on the decoded image. The spatial grid-pattern of blocks that was introduced only for the purpose of data compression becomes distinguishable in the displayed decoded picture. The image quality of the picture is, after decoding, strongly degraded.

The international patent application WO 98/41025 discloses a method for removing blocking artefacts based on the image content of the frame in the environment of the block boundary. The number of pixels to be examined and filtered depends for instance on tonal value change among pixels and the size of the quantisation step.

## SUMMARY OF THE INVENTION

It is an object of the invention to improve the image quality of a decoded picture by proposing another type of method for reducing blocking artefacts that occur at the boundary of two blocks.

5 To this end the invention relates to a decoding method such as defined in the preamble of the description, wherein said filtering step is applied only if the two pixels at the ends of said segment have chrominance components that agree with a similarity criterion.

The invention consists therefore in the definition of a conditional filtering step. This decoding method is a good trade-off between efficiency and complexity. Filtering is only  
10 performed on two adjacent blocks having chrominance components close enough to each other, which means that the blocks have similar colors near their boundary.

More precisely, said filtering step comprises the sub-steps of :

- comparing the respective chrominance components of the two pixels ;
- filtering only if the difference between said respective chrominance components is  
15 lower than a predetermined threshold.

These sub-steps of comparison of the difference of the two chrominance components with a predetermined threshold and corresponding decision allow a simple implementation of the criterion.

In improved embodiments further conditions on the pixels chrominance values or  
20 conditions on the luminance values can be added to the method. The mentioned filtering step is then aimed at eliminating blocking artefacts as much as possible while preserving image sharpness and details.

The invention also relates, for carrying out the method, to a device for decoding data corresponding to a sequence of pictures previously divided into blocks and coded,  
25 including means for decoding and means for filtering a selected segment of consecutive pixels located on both sides of any boundary between two blocks, with at least one pixel on each side of the boundary, wherein it also comprises switching means for replacing said filtering means by a direct connection if the two pixels at the ends of said segment have chrominance components that do not agree with a similarity criterion.

30

## BRIEF DESCRIPTION OF THE DRAWINGS

The particular aspects of the invention will now be explained with reference to the embodiments described hereinafter and considered in connection with the accompanying drawings, in which :

- 35 - Fig.1 depicts a prior art decoding device including a filtering circuit for the pictures to be displayed ;

- Fig.2 represents a segment of consecutive pixels straddling a block boundary in the method according to the invention ;
- Fig.3 shows a state machine diagram of a decoding method according to the present invention ;
- 5 - Fig.4 shows an improved state machine diagram of a decoding method according to the present invention ;
- Fig.5 shows an improved state machine diagram of a decoding method according to the present invention ;
- 10 - Fig.6 depicts a decoding device including a filtering circuit for carrying a method according to the invention.

#### DETAILED DESCRIPTION OF THE INVENTION

An example of a decoding device according to the prior art is shown in Fig.1. An encoding channel ENC, where each picture is divided into blocks of pixels and encoded, receives a sequence of pictures. The encoding channel ENC usually comprises discrete cosine transform and quantisation in order to provide data in a compressed form. The coded picture is directed to a decoder DEC, which produces a decoded differential picture. This differential decoded picture is summed in an adder S with the prediction picture, issued from the prediction stage PRED and formed on the basis of a previous picture, this sum resulting in a decoded picture. This decoded picture is directed to a filter FILT and after filtering provided to a screen display DISP and simultaneously stored in a picture memory MEM. For decoding the next picture, the one stored in the picture memory is read as a reference picture and transformed into a new prediction picture in the prediction stage PRED.

Fig.2 illustrates the position of a segment of 12 selected pixels on both sides of a vertical block boundary. In the considered segment, the pixels belonging to the left block are called L1, L2, L3 and so on, according to their distance to the boundary. Similarly the pixels belonging to the right block are called R1, ..., R6. The number of considered pixels is arbitrary and the segment is not necessarily symmetrical in relation to the boundary. The boundary divides the segment into two parts, each part belonging to one of the blocks. It is also within the scope of the invention to consider pixels on a single column straddling a horizontal boundary between two blocks located on two adjacent lines of blocks.

Due to the above-mentioned quantisation process, the pixels from the right and left blocks can, after decoding, be different even if they were similar in the original picture. A filter applied to the pixels located on each side of the boundary cancels or reduces this difference.

However, if this filtering step is carried out without any discrimination on a boundary, fine details located at its vicinity may disappear, a blurred picture being then

obtained. According to the invention, a criterion is chosen for determining what boundaries have indeed to be filtered. To this end it is assumed that two different objects can be best differentiated by their colors and, as a result, filtering is performed when one object only is detected on both sides of the boundary of two blocks.

5           According to the present invention, said filtering step is applied only if the two pixels at the ends of said segment have chrominance components that agree with a similarity criterion. Fig.3 shows a diagram of the steps of a decoding method integrating a simple similarity criterion. This similarity criterion allows to classify the blocks in two categories: the ones that have to be filtered and the ones that have not. The method based  
10           on Fig.3 is applied to a segment of 6 consecutive pixels {L3, L2, L1, R1, R2, R3} when using the indices of Fig.2. The similarity criterion is based on the chrominance components R, G, B of the two pixels R3, L3 at the ends of the segment. A step 2 consists in evaluating the chrominance components R, G, B of R3 and L3 and then a following step 1 in comparing the  
15           difference of those components with a given threshold  $t_1$ . If the difference is greater than  $t_1$ , filtering is not performed, otherwise filtering is performed on all the pixels of the segment. Filtering can consist in an update of the luminance components of all the pixels of the segment. If an update is decided the pixels L2, L1, R1, R2 are computed again by a simple linear interpolation between L3 and R3. This way of updating is by no means a limitation of the invention.

20           This method can be improved by adding another condition to the filtering step. Fig.4 shows a diagram of an improved implementation of the method according to the invention. Said filtering step is now applied only if the two pixels at the ends of one of the parts of said segment have luminance components that agree with a similarity criterion. This criterion allows to detect a fine detail that can exist in one block at the frontier with the  
25           other block. The criterion used in the implementation of the method illustrated in Fig.4 consists, in a step 3, in a comparison of the absolute value of the difference of the luminance of L1 and L3 with a predetermined threshold  $t_2$ . Thus, step 3 is performed and, if L1 and L3 agree with said criterion, step 2 and finally step 1 are performed. Fig.4 shows a way of implementing the method step 3 placed before the pair {step2, step1}. It must be  
30           understood that another method can be performed the other way round (step 2, step 1 followed by step3). Moreover this criterion applied to the pixels of left block only can be applied, either way, to the pixels of right block only or to both concerned blocks.

          Referring now to Fig.5, the filtering step is now applied only if the two consecutive pixels of said segment located on each side of the boundary have luminance components  
35           that agree with a similarity criterion. A step 5 is added to the method described above. This step consists in comparing the absolute value of the difference of the luminance values of the two pixels L1, R1 located on each side of the boundary. This new condition prevents

from filtering the two blocks if the difference between the two blocks is not due to a blocking artefact but to the presence of a detail at the boundary. Fig.5 comprises this new step 5, the steps 1, 2, 3 described previously and a step 4 corresponding to the step 3 performed in the same way on the right block. Again the order of implementation of the steps of the method is totally arbitrary.

So far when filtering is decided, updating has to be performed on the luminance components. However updating can be carried out on the chrominance components.

Turning now to Fig.6, there is shown a block diagram of one embodiment of a decoding device according to the present invention. The device comprises a decoder DEC that receives coded data as a bitstream from an encoder ENC and, placed at the output of the decoder DEC, filtering means FILT for removing errors resulting from data compression. For carrying out a method according to the invention, the decoding device comprises as well switching means SWIT for replacing the filtering means FILT by a direct connection when, according to the invention, the decision not to filter is taken. The switching means SWIT are placed in parallel to the filtering means FILT and according to the digital data received from the decoder DEC establish a direct connection via the connecting line cl when necessary, while the filtering means FILT are no longer connected if said direct connection is established.

## Claims

1. A method for decoding data representing a sequence of pictures previously divided into blocks and coded, including, for each successive picture, at least the steps of :
- 5       - decoding said data ;  
      - filtering the decoded data ;  
said filtering step being applied to at least one pixel component of a selected segment of consecutive pixels located on a single line or column of the current picture and on both sides of a boundary between two blocks, so that the boundary divides the segment in two parts ;
- 10       a method for decoding wherein,  
said filtering step is applied only if the two pixels at the ends of said segment have chrominance components that agree with a similarity criterion.
2. A decoding method as claimed in claim 1, wherein said filtering step comprises the
- 15       sub-steps of :  
      - comparing the respective chrominance components of the two pixels ;  
      - filtering only if the difference between said respective chrominance components is lower than a predetermined threshold.
- 20       3. A decoding method as claimed in claim 1 or 2, wherein said filtering step is applied only if the two pixels at the ends of a part of said segment have luminance components that agree with a similarity criterion.
4. A decoding method as claimed in claim 1 or 2, wherein said filtering step is applied
- 25       only if, for each part of the segment, the two pixels at the ends of the part of said segment have luminance components that agree with a similarity criterion.
5. A decoding method as claimed in claim 3 or 4, wherein said filtering step is applied only if the two consecutive pixels of said segment located on each side of the boundary have
- 30       luminance components that agree with a similarity criterion.
6. A device for decoding data corresponding to a sequence of pictures previously divided into blocks and coded, including means for decoding the coded data and means for filtering a selected segment of consecutive pixels located on both sides of any boundary
- 35       between two blocks, with at least one pixel on each side of the boundary, wherein it also comprises switching means for replacing said filtering means by a direct connection if the

two pixels at the ends of said segment have chrominance components that do not agree with a similarity criterion.
